

(a) Suppose $s_1 = 10$ and $s_i = 1$ for all $i > 1$; and $x_i = 11$ for all i . Then the optimal solution should re-boot in every other day, thereby processing 10 terabytes every two days.

(b) This problem has quite a few correct dynamic programming solutions; we describe several of the more natural ones here.

1. Let $\text{Opt}(i, j)$ denote the maximum amount of work that can be done starting from day i through day n , given the last reboot occurred j days prior, i.e., the system was rebooted on day $i - j$.

On each day, there are two options:

- *Reboot*: which means you don't process anything on day i and day $i + 1$ is the first day after the reboot. Hence, the optimal solution in this case is

$$\text{Opt}(i, j) = \text{Opt}(i + 1, 1).$$

- *Continue Processing*: which means that on day i you process the minimum of x_i and s_j . Hence, the optimal solution in this case is

$$\text{Opt}(i, j) = \min\{x_i, s_j\} + \text{Opt}(i + 1, j + 1).$$

On the last day, there is no advantage gained in rebooting and hence

$$\text{Opt}(n, j) = \min\{x_n, s_j\}$$

The Algorithm:

```

Set  $\text{Opt}(n, j) = \min\{x_n, s_j\}$ , for all  $j$  from 1 to  $n$ 
for  $i = n - 1$  downto 1
  for  $j = 1$  to  $i$ 
     $\text{Opt}(i, j) = \max\{ \text{Opt}(i + 1, 1), \min\{x_i, s_j\} + \text{Opt}(i + 1, j + 1) \}$ 
  endforj
endfori
return  $\text{Opt}(1, 1)$ 

```

Running Time: Note that the \max is over only 2 values and hence is a constant time operation. Since there are only $O(n^2)$ values being calculated, and each one takes $O(1)$ time to calculate, the algorithm takes $O(n^2)$ time.

2. Let $\text{Opt}(i, j)$ to be the maximum number of terabytes that can be processed from days 1 to i , given that the last reboot occurred j days prior to the current day.

When $j > 0$ (i.e., the system is not rebooted on day i), $\min\{x_i, s_j\}$ terabytes are processed and hence,

$$\text{Opt}(i, j) = \text{Opt}(i - 1, j - 1) + \min\{x_i, s_j\}$$

¹ex736.816.103

When $j = 0$ (i.e., the system is rebooted on day i), no processing is done on day i . Also, the previous reboot could have happened on any of the days prior to day i . Hence,

$$\text{Opt}(i, 0) = \max_{k=1}^{i-1} \{\text{Opt}(i-1, k)\}$$

Strictly speaking k should run from 0 to $i-1$, i.e., the last reboot could have happened either on day $i-1$ or on day $i-2$ and so on ... or on day 0 (which means no previous reboot). In our case, however, it is not advantageous to reboot on 2 successive days – you might as well do some computation on the first day and reboot on the second day. Since there is a reboot on day i , we can be sure that there is no reboot on day $i-1$, and hence k starts from 1.

The base case for the recursion is:

$$\text{Opt}(0, j) = 0, \forall j = 0, 1, \dots, n$$

A simple algorithm calculating the $\text{Opt}(i, j)$ values can be designed as before taking care that i runs from 1 to n . The final value to be returned is $\max_{j=1}^n \{\text{Opt}(n, j)\}$.

Running Time: All $\text{Opt}(i, j)$ values take $O(1)$ time when $j \neq 0$. $\text{Opt}(i, 0)$ values take $O(n)$ time. Hence the algorithm runs in $n^2 \times O(1) + n \times O(n) = O(n^2)$ time.

3. Let $\text{Opt}(i)$ denote the maximum number of bytes that can be processed starting from day 1 to day i . Suppose that the system was last rebooted on day $j < i$ ($j = 0$ means there was no reboot). Then since day $j+1$, the total number of bytes processed will be $b_{ji} = \sum_{k=1}^{i-j} \min\{x_{j+k}, s_k\}$. (Remember that there is no use rebooting on the last day.) The total work processed till day i would then be $\text{Opt}(j-1) + b_{ji}$. To get the maximum number of bytes processed, maximize over all values of $j < i$. Hence,

$$\text{Opt}(i) = \max_{j=0}^{i-1} \{\text{Opt}(j)\} + b_{ji}$$

The base case:

$$\text{Opt}(0) = 0$$

Compute $\text{Opt}(i)$ values starting from $i = 1$ and return the value of $\text{Opt}(n)$.

Running Time: Each b_{ji} value takes $O(n)$ time to calculate, and since there are $O(n^2)$ such values being calculated, the algorithm takes, $O(n^3)$ time.
