

Let B denote the set of nodes on the *border* of the grid G — i.e. the outermost rows and columns. Say that G has *Property (*)* if it contains a node $v \notin B$ that is adjacent to a node in B and satisfies $v \prec B$. Note that in a grid G with Property (*), the *global minimum* does not occur on the border B (since the global minimum is no larger than v , which is smaller than B) — hence G has at least one local minimum that does not occur on the border. We call such a local minimum an *internal local minimum*.

We now describe a recursive algorithm that takes a grid satisfying Property (*) and returns an internal local minimum, using $O(n)$ probes. At the end, we will describe how this can be easily converted into a solution for the overall problem.

Thus, let G satisfy Property (*), and let $v \notin B$ be adjacent to a node in B and smaller than all nodes in B . Let C denote the union of the nodes in the middle row and middle column of G , not counting the nodes on the border. Let $S = B \cup C$; deleting S from G divides up G into four sub-grids. Finally, let T be all nodes adjacent to S .

Using $O(n)$ probes, we find the node $u \in S \cup T$ of minimum value. We know that $u \notin B$, since $v \in S \cup T$ and $v \prec B$. Thus, we have two cases. If $u \in C$, then u is an internal local minimum, since all of the neighbors of u are in $S \cup T$, and u is smaller than all of them. Otherwise, $u \in T$. Let G' be the sub-grid containing u , together with the portions of S that border it. Now, G' satisfies Property (*), since u is adjacent to the border of G' and is smaller than all nodes on the border of G' . Thus, G' has an internal local minimum, which is also an internal local minimum of G . We call our algorithm recursively on G' to find such an internal local minimum.

If $T(n)$ denotes the number of probes needed by the algorithm to find an internal local minimum in an $n \times n$ grid, we have the recurrence $T(n) = O(n) + T(n/2)$, which solves to $T(n) = O(n)$.

Finally, we convert this into an algorithm to find a local minimum (not necessarily internal) of a grid G . Using $O(n)$ probes, we find the node v on the border B of minimum value. If v is a corner node, it is a local minimum and we're done. Otherwise, v has a unique neighbor u not on B . If $v \prec u$, then v is a local minimum and again we're done. Otherwise, G satisfies Property (*) (since u is smaller than every node on B), and we call the above algorithm.
